coef.dynr_model	<i>Auto and Cross Regression Coefficients</i>
-----------------	---

Description

Auto and Cross Regression Coefficients

Usage

```
## S3 method for class 'dynr_model'
coef(object, dynr_cook, ...)
```

Arguments

object	Object of class dynr_model.
dynr_cook	Ouput of FitVARDynr() .
...	additional arguments.

Value

A list with the following elements:

- constant Numeric vector. The constant term vector of length k, where k is the number of variables.
- coef Numeric matrix. Coefficient matrix with dimensions k by (k * p). Each k by k block corresponds to the coefficient matrix for a particular lag.
- cov Numeric matrix. The k by k covariance matrix of the noise.

Author(s)

Ivan Jacob Agaloos Pesigan

Examples

```
## Not run:
dynr_model <- ModelVARP2Dynr(data = dat_demo)
dynr_cook <- FitVARP2Dynr(model = dynr_model)
coef(object = dynr_model, dynr_cook = dynr_cook)

## End(Not run)
```

dat_demo

*Data from the Vector Autoregressive Model***Description**

Data from the Vector Autoregressive Model

Usage

dat_demo

Format

A matrix with 1000 rows (time points) and $k = 3$ columns (variables) generated from the $p = 2$ vector autoregressive model given by

$$Y_{1t} = 1 + 0.4Y_{1t-1} + 0.0Y_{2t-1} + 0.0Y_{3t-1} + 0.1Y_{1t-2} + 0.0Y_{2t-2} + 0.0Y_{3t-2} + \varepsilon_{1t},$$

$$Y_{2t} = 1 + 0.0Y_{1t-1} + 0.5Y_{2t-1} + 0.0Y_{3t-1} + 0.0Y_{1t-2} + 0.2Y_{2t-2} + 0.0Y_{3t-2} + \varepsilon_{2t},$$

and

$$Y_{3t} = 1 + 0.0Y_{1t-1} + 0.0Y_{2t-1} + 0.6Y_{3t-1} + 0.0Y_{1t-2} + 0.0Y_{2t-2} + 0.3Y_{3t-2} + \varepsilon_{3t}$$

which simplifies to

$$Y_{1t} = 1 + 0.4Y_{1t-1} + 0.1Y_{1t-2} + \varepsilon_{1t},$$

$$Y_{2t} = 1 + 0.5Y_{2t-1} + 0.2Y_{2t-2} + \varepsilon_{2t},$$

and

$$Y_{3t} = 1 + 0.6Y_{3t-1} + 0.3Y_{3t-2} + \varepsilon_{3t}.$$

The covariance matrix of process noise is an identity matrix.

dat_demo_exo

Data from the Vector Autoregressive Model with Exogenous Variables

Description

Data from the Vector Autoregressive Model with Exogenous Variables

Usage

dat_demo_exo

Format

A matrix with 1000 rows (time points) and $k = 3$ (autoregressive variables) plus $m = 3$ columns (exogenous variables) generated from the $p = 2$ vector autoregressive model given by

$$Y_{1t} = 1 + 0.4Y_{1t-1} + 0.0Y_{2t-1} + 0.0Y_{3t-1} + 0.1Y_{1t-2} + 0.0Y_{2t-2} + 0.0Y_{3t-2} + 0.5X_1 + 0.0X_2 + 0.0X_3\varepsilon_{1t},$$

$$Y_{2t} = 1 + 0.0Y_{1t-1} + 0.5Y_{2t-1} + 0.0Y_{3t-1} + 0.0Y_{1t-2} + 0.2Y_{2t-2} + 0.0Y_{3t-2} + 0.0X_1 + 0.5X_2 + 0.0X_3\varepsilon_{2t},$$

and

$$Y_{3t} = 1 + 0.0Y_{1t-1} + 0.0Y_{2t-1} + 0.6Y_{3t-1} + 0.0Y_{1t-2} + 0.0Y_{2t-2} + 0.3Y_{3t-2} + 0.0X_1 + 0.0X_2 + 0.5X_3\varepsilon_{3t}$$

which simplifies to

$$Y_{1t} = 1 + 0.4Y_{1t-1} + 0.1Y_{1t-2} + 0.5X_1\varepsilon_{1t},$$

$$Y_{2t} = 1 + 0.5Y_{2t-1} + 0.2Y_{2t-2} + 0.5X_2\varepsilon_{2t},$$

and

$$Y_{3t} = 1 + 0.6Y_{3t-1} + 0.3Y_{3t-2} + 0.5X_3\varepsilon_{3t}.$$

The covariance matrix of process noise is an identity matrix.

dat_demo_exo_yx

Data from the Vector Autoregressive Model (Y) and Lagged Predictors and Exogenous Variables (X)

Description

Data from the Vector Autoregressive Model (Y) and Lagged Predictors and Exogenous Variables (X)

Usage

dat_demo_exo_yx

Format

A list with elements Y and X where Y is equal to the $k = 3$ autoregressive variables of the dat_demo_exo data set minus $p = 2$ terminal rows and X is a matrix of ones for the first column, lagged values of Y, and $m = 3$ exogenous variables.

dat_demo_yx	<i>Data from the Vector Autoregressive Model (Y) and Lagged Predictors (X)</i>
-------------	--

Description

Data from the Vector Autoregressive Model (Y) and Lagged Predictors (X)

Usage

```
dat_demo_yx
```

Format

A list with elements Y and X where Y is equal to the dat_demo data set minus p = 2 terminal rows and X is a matrix of ones for the first column and lagged values of Y for the rest of the columns.

FitMLVARDynr	<i>Fit Vector Autoregressive (VAR) Model using dynr on Each of the Data Matrix in a List</i>
--------------	--

Description

This function estimates the parameters of a VAR model using the dynr package for each of the data matrix in a list.

Usage

```
FitMLVARDynr(
  data,
  p,
  ncores = 1,
  conf_level = 0.95,
  optimization_flag = TRUE,
  hessian_flag = TRUE,
  verbose = FALSE,
  weight_flag = FALSE,
  debug_flag = FALSE,
  perturb_flag = FALSE
)
```

Arguments

<code>data</code>	List. Each element is a numeric matrix of time series data with dimensions t by k , where t is the number of observations and k is the number of variables.
<code>p</code>	Positive integer. Number of lags. Only supports $p = 1$ and $p = 2$.
<code>ncores</code>	Positive integer. Number of cores to use. Not supported on Windows.
<code>conf_level</code>	a cumulative proportion indicating the level of desired confidence intervals for the final parameter estimates (default is .95)
<code>optimization_flag</code>	a flag (TRUE/FALSE) indicating whether optimization is to be done.
<code>hessian_flag</code>	a flag (TRUE/FALSE) indicating whether the Hessian matrix is to be calculated.
<code>verbose</code>	a flag (TRUE/FALSE) indicating whether more detailed intermediate output during the estimation process should be printed
<code>weight_flag</code>	a flag (TRUE/FALSE) indicating whether the negative log likelihood function should be weighted by the length of the time series for each individual
<code>debug_flag</code>	a flag (TRUE/FALSE) indicating whether users want additional dynr output that can be used for diagnostic purposes
<code>perturb_flag</code>	a flag (TRUE/FLASE) indicating whether to perturb the latent states during estimation. Only useful for ensemble forecasting.

Value

A list each element of which is an object of class `dynrCook`.

FitVARDynr

Fit Vector Autoregressive (VAR($p = 2$)) Model using dynr

Description

This function estimates the parameters of a VAR($p = 2$) model using the `dynr` package.

Usage

```
FitVARDynr(
  model,
  conf_level = 0.95,
  optimization_flag = TRUE,
  hessian_flag = TRUE,
  verbose = FALSE,
  weight_flag = FALSE,
  debug_flag = FALSE,
  perturb_flag = FALSE
)
```

Arguments

<code>model</code>	Output of ModelVARP1Dynr() or ModelVARP2Dynr() .
<code>conf_level</code>	a cumulative proportion indicating the level of desired confidence intervals for the final parameter estimates (default is .95)
<code>optimization_flag</code>	a flag (TRUE/FALSE) indicating whether optimization is to be done.
<code>hessian_flag</code>	a flag (TRUE/FALSE) indicating whether the Hessian matrix is to be calculated.
<code>verbose</code>	a flag (TRUE/FALSE) indicating whether more detailed intermediate output during the estimation process should be printed
<code>weight_flag</code>	a flag (TRUE/FALSE) indicating whether the negative log likelihood function should be weighted by the length of the time series for each individual
<code>debug_flag</code>	a flag (TRUE/FALSE) indicating whether users want additional dynr output that can be used for diagnostic purposes
<code>perturb_flag</code>	a flag (TRUE/FLASE) indicating whether to perturb the latent states during estimation. Only useful for ensemble forecasting.

Value

Object of class `dynrCook`.

```

FitVARLasso	<i>Fit Vector Autoregressive (VAR) Model Parameters using Lasso Regularization</i>
-------------	--

Description

This function estimates the parameters of a VAR model using the Lasso regularization method with cyclical coordinate descent. The Lasso method is used to estimate the autoregressive and cross-regression coefficients with sparsity.

Usage

```
FitVARLasso(Ystd, Xstd, lambda, max_iter, tol)
```

Arguments

<code>Ystd</code>	Numeric matrix. Matrix of standardized dependent variables (Y).
<code>Xstd</code>	Numeric matrix. Matrix of standardized predictors (X).
<code>lambda</code>	Lasso hyperparameter. The regularization strength controlling the sparsity.
<code>max_iter</code>	Integer. The maximum number of iterations for the coordinate descent algorithm (e.g., <code>max_iter = 10000</code>).
<code>tol</code>	Numeric. Convergence tolerance. The algorithm stops when the change in coefficients between iterations is below this tolerance (e.g., <code>tol = 1e-5</code>).

Details

The `FitVARLasso()` function estimates the parameters of a Vector Autoregressive (VAR) model using the Lasso regularization method. Given the input matrices `Ystd` and `Xstd`, where `Ystd` is the matrix of standardized dependent variables, and `Xstd` is the matrix of standardized predictors, the function computes the autoregressive and cross-regression coefficients of the VAR model with sparsity induced by the Lasso regularization.

The steps involved in estimating the VAR model parameters using Lasso are as follows:

- **Initialization:** The function initializes the coefficient matrix `beta` with OLS estimates. The `beta` matrix will store the estimated autoregressive and cross-regression coefficients.
- **Coordinate Descent Loop:** The function performs the cyclical coordinate descent algorithm to estimate the coefficients iteratively. The loop iterates `max_iter` times, or until convergence is achieved. The outer loop iterates over the predictor variables (columns of `Xstd`), while the inner loop iterates over the outcome variables (columns of `Ystd`).

- **Coefficient Update:** For each predictor variable (column of `Xstd`), the function iteratively updates the corresponding column of `beta` using the coordinate descent algorithm with L1 norm regularization (Lasso). The update involves calculating the soft-thresholded value `c`, which encourages sparsity in the coefficients. The algorithm continues until the change in coefficients between iterations is below the specified tolerance `tol` or when the maximum number of iterations is reached.
- **Convergence Check:** The function checks for convergence by comparing the current `beta` matrix with the previous iteration's `beta_old`. If the maximum absolute difference between `beta` and `beta_old` is below the tolerance `tol`, the algorithm is considered converged, and the loop exits.

Value

Matrix of estimated autoregressive and cross-regression coefficients.

  max_iter = 10000, tol = 1e-5)
```

FitVARLassoSearch	<i>Fit Vector Autoregressive (VAR) Model Parameters using Lasso Regularization with Lambda Search</i>
-------------------	---

Description

Fit Vector Autoregressive (VAR) Model Parameters using Lasso Regularization with Lambda Search

Usage

```
FitVARLassoSearch(Ystd, Xstd, lambdas, crit, max_iter, tol)
```

Arguments

<code>Ystd</code>	Numeric matrix. Matrix of standardized dependent variables (Y).
<code>Xstd</code>	Numeric matrix. Matrix of standardized predictors (X).
<code>lambdas</code>	Numeric vector. Vector of lambda hyperparameters for Lasso regularization.
<code>crit</code>	Character string. Information criteria to use. Valid values include "aic", "bic", and "ebic".
<code>max_iter</code>	Integer. The maximum number of iterations for the coordinate descent algorithm (e.g., <code>max_iter = 10000</code>).
<code>tol</code>	Numeric. Convergence tolerance. The algorithm stops when the change in coefficients between iterations is below this tolerance (e.g., <code>tol = 1e-5</code>).

  crit = "ebic", max_iter = 1000, tol = 1e-5)
```

FitVAROLS

Fit Vector Autoregressive (VAR) Model Parameters using OLS

Description

This function estimates the parameters of a VAR model using the Ordinary Least Squares (OLS) method. The OLS method is used to estimate the autoregressive and cross-regression coefficients.

Usage

```
FitVAROLS(Y, X)
```

Arguments

Y	Numeric matrix. Matrix of dependent variables (Y).
X	Numeric matrix. Matrix of predictors (X).

Details

The `FitVAROLS()` function estimates the parameters of a Vector Autoregressive (VAR) model using the Ordinary Least Squares (OLS) method. Given the input matrices Y and X, where Y is the matrix of dependent variables, and X is the matrix of predictors, the function computes the autoregressive and cross-regression coefficients of the VAR model. Note that if the first column of X is a vector of ones, the constant vector is also estimated.

The steps involved in estimating the VAR model parameters using OLS are as follows:

- Compute the QR decomposition of the lagged predictor matrix X using the `qr` function from the Armadillo library.
- Extract the Q and R matrices from the QR decomposition.
- Solve the linear system $R * \text{coef} = Q.t() * Y$ to estimate the VAR model coefficients `coef`.
- The function returns a matrix containing the estimated autoregressive and cross-regression coefficients of the VAR model.

Value

Matrix of estimated autoregressive and cross-regression coefficients.

Author(s)

Ivan Jacob Agaloos Pesigan

Examples

```
Y <- dat_demo_yx$Y
X <- dat_demo_yx$X
FitVAROLS(Y = Y, X = X)
```

LambdaSeq	<i>Function to generate the sequence of lambdas</i>
-----------	---

Description

Function to generate the sequence of lambdas

Usage

```
LambdaSeq(Y, X, n_lambdas)
```

Arguments

Y	Numeric matrix. Matrix of dependent variables (Y).
X	Numeric matrix. Matrix of predictors (X).
n_lambdas	Integer. Number of lambdas to generate.

Value

Returns a vector of lambdas.

Examples

```
Ystd <- StdMat(dat_demo_yx$Y)
Xstd <- StdMat(dat_demo_yx$X[, -1])
LambdaSeq(Y = Ystd, X = Xstd, n_lambdas = 100)
```

ModelVARP1Dynr	<i>Specify Vector Autoregressive (VAR($p = 1$)) Model using dynr</i>
----------------	---

Description

This function specifies a VAR($p = 1$) model using the `dynr::dynr.model()` package.

Usage

```
ModelVARP1Dynr(data, outfile = tempfile())
```

Arguments

data	Numeric matrix. The time series data with dimensions t by k , where t is the number of observations and k is the number of variables.
outfile	a character string of the name of the output C script of model functions to be compiled for parameter estimation. The default is the name for a potential temporary file returned by <code>tempfile()</code> .

```

ModelVARP2Dynr	<i>Specify Vector Autoregressive (VAR($p = 2$)) Model using dynr</i>
----------------	---

Description

This function specifies a VAR($p = 2$) model using the `dynr::dynr.model()` package.

Usage

```
ModelVARP2Dynr(data, outfile = tempfile())
```

Arguments

data	Numeric matrix. The time series data with dimensions t by k , where t is the number of observations and k is the number of variables.
outfile	a character string of the name of the output C script of model functions to be compiled for parameter estimation. The default is the name for a potential temporary file returned by <code>tempfile()</code> .

```

PBootCI

Parametric Bootstrap Confidence Intervals

Description

Parametric Bootstrap Confidence Intervals

Usage

```
PBootCI(x, alpha = 0.05)
```

Arguments

x	Numeric matrix. Output of PBootVAROLS() .
alpha	Numeric. Significance level.

Value

A list with two elements, namely `ll` for the lower limit and `ul` for the upper limit.

---------------	--

Description

Parametric Bootstrap for the Vector Autoregressive Model Using Lasso Regularization

Usage

```
PBootVARLasso(data, p, B, burn_in, n_lambdas, crit, max_iter, tol)
```

Arguments

data	Numeric matrix. The time series data with dimensions t by k , where t is the number of observations and k is the number of variables.
p	Integer. The order of the VAR model (number of lags).
B	Integer. Number of bootstrap samples to generate.
burn_in	Integer. Number of burn-in observations to exclude before returning the results in the simulation step.
n_lambdas	Integer. Number of lambdas to generate.
crit	Character string. Information criteria to use. Valid values include "aic", "bic", and "ebic".
max_iter	Integer. The maximum number of iterations for the coordinate descent algorithm (e.g., <code>max_iter = 10000</code>).
tol	Numeric. Convergence tolerance. The algorithm stops when the change in coefficients between iterations is below this tolerance (e.g., <code>tol = 1e-5</code>).

Value

List containing the estimates (`est`) and bootstrap estimates (`boot`).

plot.dynr_model	<i>Plot Method for an Object of Class dynr_model</i>
-----------------	--

Description

Plot Method for an Object of Class dynr_model

Usage

```
## S3 method for class 'dynr_model'  
plot(x, ...)
```

Arguments

x	Object of class dynr_model.
...	additional arguments.

Author(s)

Ivan Jacob Agaloos Pesigan

Examples

```
model <- ModelVARP2Dynr(data = dat_demo)  
plot(model)
```

print.dynr_model	<i>Print Method for an Object of Class dynr_model</i>
------------------	---

Description

Print Method for an Object of Class dynr_model

Usage

```
## S3 method for class 'dynr_model'  
print(x, ...)
```

Arguments

x	Object of class dynr_model.
...	additional arguments.

Ivan Jacob Agaloos Pesigan

Examples

```
model <- ModelVARP2Dynr(data = dat_demo)
print(model)
```

SearchVARLasso

Compute AIC, BIC, and EBIC for Lasso Regularization

Description

This function computes the Akaike Information Criterion (AIC), Bayesian Information Criterion (BIC), and Extended Bayesian Information Criterion (EBIC) for a given matrix of predictors X , a matrix of outcomes Y , and a vector of lambda hyperparameters for Lasso regularization.

Usage

```
SearchVARLasso(Ystd, Xstd, lambdas, max_iter, tol)
```

Arguments

<code>Ystd</code>	Numeric matrix. Matrix of standardized dependent variables (Y).
<code>Xstd</code>	Numeric matrix. Matrix of standardized predictors (X).
<code>lambdas</code>	Numeric vector. Vector of lambda hyperparameters for Lasso regularization.
<code>max_iter</code>	Integer. The maximum number of iterations for the coordinate descent algorithm (e.g., <code>max_iter = 10000</code>).
<code>tol</code>	Numeric. Convergence tolerance. The algorithm stops when the change in coefficients between iterations is below this tolerance (e.g., <code>tol = 1e-5</code>).

Value

List containing two elements:

- Element 1: Matrix with columns for lambda, AIC, BIC, and EBIC values.
- Element 2: List of matrices containing the estimated autoregressive and cross-regression coefficients for each lambda.

Examples

```
Ystd <- StdMat(dat_demo_yx$Y)
Xstd <- StdMat(dat_demo_yx$X[, -1])
lambdas <- 10^seq(-5, 5, length.out = 100)
search <- SearchVARLasso(Ystd = Ystd, Xstd = Xstd, lambdas = lambdas,
  max_iter = 10000, tol = 1e-5)
plot(x = 1:nrow(search$criteria), y = search$criteria[, 4],
  type = "b", xlab = "lambda", ylab = "EBIC")
```

SelectVARLasso

Select the Lasso Estimates from the Grid Search

Description

Select the Lasso Estimates from the Grid Search

Usage

```
SelectVARLasso(search, crit = "ebic")
```

Arguments

search	Object. Output of the SearchVARLasso() function.
crit	Character string. Information criteria to use. Valid values include "aic", "bic", and "ebic".

Value

Returns the Lasso estimates of autoregression and cross regression coefficients.

```

SimVAR

Simulate Data from a Vector Autoregressive (VAR) Model

Description

This function generates synthetic time series data from a Vector Autoregressive (VAR) model.

Usage

```
SimVAR(time, burn_in, constant, coef, chol_cov)
```

Arguments

time	Integer. Number of time points to simulate.
burn_in	Integer. Number of burn-in observations to exclude before returning the results.
constant	Numeric vector. The constant term vector of length k, where k is the number of variables.
coef	Numeric matrix. Coefficient matrix with dimensions k by (k * p). Each k by k block corresponds to the coefficient matrix for a particular lag.
chol_cov	Numeric matrix. The Cholesky decomposition of the covariance matrix of the multivariate normal noise. It should have dimensions k by k.

Details

The [SimVAR\(\)](#) function generates synthetic time series data from a Vector Autoregressive (VAR) model. The VAR model is defined by the constant term constant, the coefficient matrix coef, and the Cholesky decomposition of the covariance matrix of the multivariate normal process noise chol_cov. The generated time series data follows a VAR(p) process, where p is the number of lags specified by the size of coef. The generated data includes a burn-in period, which is excluded before returning the results.

The steps involved in generating the VAR time series data are as follows:

- Extract the number of variables k and the number of lags p from the input.
- Create a matrix data of size k by (time + burn_in) to store the generated VAR time series data.

- Set the initial values of the matrix data using the constant term constant.
- For each time point starting from the p-th time point to time + burn_in - 1:
 - Generate a vector of random noise from a multivariate normal distribution with mean 0 and covariance matrix chol_cov.
 - Generate the VAR time series values for each variable j at time t using the formula:

$$Y_{tj} = constant_j + \sum_{l=1}^p \sum_{m=1}^k (coef_{jlm} * Y_{tm}) + noise_j$$

where Y_{tj} is the value of variable j at time t, $constant_j$ is the constant term for variable j, $coef_{jlm}$ are the coefficients for variable j from lagged variables up to order p, Y_{tm} are the lagged values of variable m up to order p at time t, and $noise_j$ is the element j from the generated vector of random process noise.

- Transpose the matrix data and return only the required time period after the burn-in period, which is from column burn_in to column time + burn_in - 1.

Value

Numeric matrix containing the simulated time series data with dimensions k by time, where k is the number of variables and time is the number of observations.

  )
  head(y)

```

StdMat

Standardize Matrix

Description

This function standardizes the given matrix by centering the columns and scaling them to have unit variance.

Usage

```
StdMat(X)
```

Arguments

X Numeric matrix. The matrix to be standardized.

Value

Numeric matrix with standardized values.

YX *Create Y and X Matrices*

Description

This function creates the dependent variable (Y) and predictor variable (X) matrices.

Usage

```
YX(data, p)
```

Arguments

data	Numeric matrix. The time series data with dimensions t by k , where t is the number of observations and k is the number of variables.
p	Integer. The order of the VAR model (number of lags).

Details

The `YX()` function creates the Y and X matrices required for fitting a Vector Autoregressive (VAR) model. Given the input data matrix with dimensions t by k , where t is the number of observations and k is the number of variables, and the order of the VAR model p (number of lags), the function constructs lagged predictor matrix X and the dependent variable matrix Y.

The steps involved in creating the Y and X matrices are as follows:

- Determine the number of observations t and the number of variables k from the input data matrix.
- Create matrices X and Y to store lagged variables and the dependent variable, respectively.
- Populate the matrices X and Y with the appropriate lagged data. The predictors matrix X contains a column of ones and the lagged values of the dependent variables, while the dependent variable matrix Y contains the original values of the dependent variables.
- The function returns a list containing the Y and X matrices, which can be used for further analysis and estimation of the VAR model parameters.

Value

List containing the dependent variable (Y) and predictor variable (X) matrices. Note that the resulting matrices will have $t - p$ rows.
